A* SEARCH ALGORITHM

A heuristic algorithm sacrifices optimality, with precision and accuracy for speed, to solve problems faster and more efficiently.

All graphs have different nodes or points which the algorithm has to take, to reach the final node. The paths between these nodes all have a numerical value, which is considered as the weight of the path. The total of all paths transverse gives you the cost of that route.

Initially, the Algorithm calculates the cost to all its immediate neighboring nodes,n, and chooses the one incurring the least cost. This process repeats until no new nodes can be chosen and all paths have been traversed. Then, you should consider the best path among them. If f(n) represents the final cost, then it can be denoted as:

- f(n) = g(n) + h(n), where :
- g(n) = cost of traversing from one node to another. This will vary from node to node
- h(n) = heuristic approximation of the node's value. This is not a real value but an approximation cost.

AIM:

To implement an A* search algorithm using Python.

SOURCE CODE:

from collections import deque

```
class Graph:
    def __init__(self, adjac_lis):
        self.adjac_lis = adjac_lis

def get_neighbors(self, v):
```

```
return self.adjac lis[v]
def h(self, n):
  H = {
     'A': 1,
     'B': 1,
     'C': 1,
     'D': 1
  return H[n]
def a star algorithm(self, start, stop):
  open lst = set([start])
  closed lst = set([])
  poo = \{\}
  poo[start] = 0
  par = \{\}
  par[start] = start
  while len(open lst) > 0:
     n = None
     for v in open 1st:
       if n == None \text{ or } poo[v] + self.h(v) < poo[n] + self.h(n):
          n = v;
     if n == None:
       print('Path does not exist!')
       return None
     if n == stop:
       reconst path = []
       while par[n] != n:
          reconst path.append(n)
          n = par[n]
       reconst path.append(start)
       reconst path.reverse()
       print('Path found: {}'.format(reconst path))
       return reconst path
```

```
for (m, weight) in self.get neighbors(n):
        # if the current node is not present in both open 1st and closed 1st
         if m not in open 1st and m not in closed 1st:
            open lst.add(m)
            par[m] = n
            poo[m] = poo[n] + weight
            if poo[m] > poo[n] + weight:
              poo[m] = poo[n] + weight
              par[m] = n
              if m in closed 1st:
                 closed lst.remove(m)
                 open lst.add(m)
       open lst.remove(n)
       closed lst.add(n)
    print('Path does not exist!')
    return None
adjac lis = {
  'A': [('B', 1), ('C', 3), ('D', 7)],
  'B': [('D', 5)],
  'C': [('D', 12)]
}
graph1 = Graph(adjac lis)
graph1.a star algorithm('A', 'D')
OUTPUT:
Path found: ['A', 'B',
```

RESULT:

Thus the program to implement an A* search algorithm using Python is successfully executed.
